Texponse Project Status

An AI assistant that replies to customer texts automatically and remembers the conversation.

Completed

1. **App starts.** Fixed three startup crashes: outdated knowledge database code, broken user account definitions, and missing record IDs.
2. **Answers generate.** The pipeline works end to end: incoming text, knowledge search, AI reply, saved reply. Replies take about 4 seconds.
3. **Aircall connected.** Fixed the send method and enabled line 1244782 for automated texting. A live inbound text ("Hi hi") passed through the full system.
4. **Results visible.** The test button now returns the actual answer or the exact error, not just "queued."
5. **Cleanup done.** All automated checks pass.

Current Status

Done: The app runs, the AI replies, and replies are stored.

Done: Outbound texting works. Aircall blocks a number from texting itself. That is their rule, not a bug.

Pending: Inbound auto-replies need the Aircall callback set to /webhooks/aircall/callback.

Required Services

The app relies on four outside services. Each needs an account key.

OpenRouter writes the AI replies. API key added. Switched to the openrouter/free router after old model names expired.

Aircall sends and receives texts. API login done. Line 1244782 enabled for automation. A number can use the app or automation, not both.

Jobber supplies customer name, jobs, and history. The developer app is not yet created. Without it, replies lack customer context.

ngrok gives Aircall a temporary public address during testing. Set up and working.

Next Step: Jobber

1. Create a free Jobber developer app.
2. Approve it once in a browser.
3. Save the login token in the database.

No code changes are needed. After this, every incoming text includes the customer's Jobber record.
